

SoPHIE: Social Robotic Platform for Human Interactive Experimentation

Target Application: Dialog Analysis by Bayesian Multimodal Observation on an Assistant Robot

José Prado, Jorge Lobo and Jorge Dias

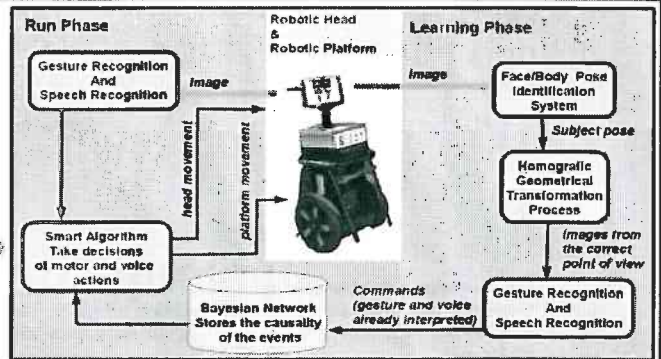

SoPHIE, the social robot:

The aim of the SoPHIE-project is to develop a multipurpose platform to investigate social interaction between humans and robots. The objective of its first version is to classify gestures and voice commands performed by two human actors performing a dialog (with a simplified language). SoPHIE vision uses a series of images taken by a stereo pair of cameras while its audition is based on a pair of microphones.

In the figure aside a schema of the processes involved on the analysis algorithm. Each block then is explained briefly below.

Previous experimentation about Bayesian Learning were already done by the author at [3], [4], [5] and [6].

Homography Geometrical Transformation Process

Our gesture recognition algorithm analyzes the gestures based on the intrinsic parameters of the triangle that links head and hands [2]. So, what really matters is the proportional changes among the side's sizes and angles of it. Thus, we can say that the scale factor of the gesture triangle is irrelevant once guaranteed that the 3 corners (hands and face) are inside the camera field of view. Considering this, and the figure aside, it is possible to remove the perspective projection. Then a virtual point of view, aligned to the other interlocutor is given to the robot.

Bayesian Network Stores the causality of the events

$P(C)$ = Uniform
 $P(R|C)$ = acquired from learning by observation
 $P(R)$ = Uniform
 $P(C|R) = \frac{P(C) \cdot P(R|C)}{P(R)}$

Based on Independence theorem

$P(L|C) = P(L) \cdot P(C|L) = P(C)$
 Where:
 G = gesture
 S = sound (from human source)
 E = emotion
 L = laser, collision avoidance
 C = Command
 R = Response

$$P(R|L, C)P(C|G, E, S)P(L)P(G)P(E)P(S)$$

Main Applications of Social Robots:

Security, Research, Health Care, Personal Assistant / Interface, toys, Business, Pet, Entertainment, Teacher, Transport, Companionship, Caregiver, Public Assistant

Face/Body Pose Identification System

Detecting face and hands

Without skin colour at the background Problem occurs: With skin colour at the background

Solution - Horopter based Background [1][2]

Without background segmentation With background segmentation

Without background segmentation With background segmentation

Gesture Recognition and Speech Recognition

In [5] we concluded that horopter is a valid approach for dynamic background segmentation, provided that it receives background with enough features, which usually happens. This segmentation enhances tracking results, both in speed and accuracy and should be further explored. Laban Movement Analysis is without a doubt a powerful movement descriptive tool, results show that it can, with some accuracy classify basic emotion primitives (contextualized within LMA), and the implementation of the remaining components is an ongoing work. To build an autonomous interactive multimodal social robot, we are here combining our current gesture classification algorithm [5] with the capability of auditory perception and dialog analysis.

Smart Algorithm take decisions of motor and voice actions

The main contributions of work [7] were the probabilistic description of the spoken dialogue process for simulation purposes. However, it was used a simple Bayesian Model that remains with static relationships between the variables. Our proposal is to develop a Dynamic Bayesian Network (DBN). Description of work Initially it is necessary to correctly setup a tool for speech recognition. The selected tool is the Dragon Naturally Speaking software by Nuance. Our dialog analysis will be limited for one interlocutor speaking at a time, and also each interlocutor must be equipped with a microphone near to the mouth. We are also going to perform tests with Directional Microphones.
